3 Function Calls

4 Function Prototypes and Header Files

5 Assignment

The cctype Library

cctype Functions

<code>bool isalpha(char c);</code>	<code>bool isblank(char c);</code>
<code>bool islower(char c);</code>	<code>bool iscntrl(char c);</code>
<code>bool isupper(char c);</code>	<code>bool isgraph(char c);</code>
<code>bool isdigit(char c);</code>	<code>bool isprint(char c);</code>
<code>bool isxdigit(char c);</code>	<code>bool isspace(char c);</code>
<code>bool isalnum(char c);</code>	<code>void tolower(char c);</code>
<code>bool ispunct(char c);</code>	<code>void toupper(char c);</code>

- `isxdigit()` – Returns `true` if the character is a hexadecimal digit.
- `iscntrl()` – Returns `true` if the character is a control character.

Outline

1 The ctype Library

2 Programmer-Defined Functions

- The Form
- Examples

3 Function Calls

4 Function Prototypes and Header Files

5 Assignment

Programmer-Defined Functions

- A programmer may create his own functions.
- If his function is invoked in `main()`, then
 - Execution leaves `main()` (which is itself a function) and goes to the function.
 - The function executes as a program in its own right.
 - When the function is finished, execution returns to `main()` and continues.

Outline

1 The ctype Library

2 Programmer-Defined Functions

- The Form
- Examples

3 Function Calls

4 Function Prototypes and Header Files

5 Assignment

The Form of a Function

The Form of a Function

```
return-type function-name(formal-param-list)
{
    function-body
    return return-value;
}
```

- *function-name* is the name that the programmer chooses for the function.
- The *formal-param-list* is a list of object types and names passed to the function as parameters.
- The *function-body* is a sequence of C++ statements that will compute the appropriate value for the returned object.

The Form of a Function

The Form of a Function

```
return-type function-name(formal-param-list)
{
    function-body
    return return-value;
}
```

- *return-type* is the type of object that the function returns to the **calling function**.
- *return-value* must be of type *return-type*.
- *return-type* may be **void**, in which case the **return** statement is optional.
 - If it is written, then there is no return value specified.

Outline

1 The ctype Library

2 Programmer-Defined Functions

- The Form
- Examples

3 Function Calls

4 Function Prototypes and Header Files

5 Assignment

Example of a Function

Function Definition

```
float average3(float a, float b, float c)
{
    float avg = (a + b + c) / 3.0;
    return avg;
}
```

- This function will return the average of three numbers.

Example of a Function

Function Definition

```
float average3(float a, float b, float c)
{
    return (a + b + c) / 3.0;
}
```

- It is legal to return the value of an expression.

Outline

1 The ctype Library

2 Programmer-Defined Functions

- The Form
- Examples

3 Function Calls

4 Function Prototypes and Header Files

5 Assignment

Function Calls

Function Call

function-name (actual-param-list)

- The *actual-param-list* is a list of actual objects or expressions.
- A **function call** occurs in an expression.
- If the function is **void** type, then the function call is a complete statement and must occur on a line by itself.
- If the function is not **void** type, then the function call occurs within an expression where an object of the function type is permitted.

Function Usage

- Data types are not specified in the actual parameter list.
- Actual vs. formal parameters
 - Types must match, or else
 - There must be a conversion rule to convert the actual type into the formal type.

Example of Function Usage

Function Usage

```
cout << "Enter the three grades:  ";
float grade1, grade2, grade3;
cin >> grade1 >> grade2 >> grade3;
float avg_grade = average3(grade1, grade2, grade3)
cout << avg_grade << endl;
```

- This program finds the average of three grades.

Example of Function Usage

Function Usage

```
cout << "Enter the three grades: ";
float grade1, grade2, grade3;
cin >> grade1 >> grade2 >> grade3;
cout << average3(grade1, grade2, grade3) << endl;
```

- The function call may be placed in the output statement.

Outline

1 The ctype Library

2 Programmer-Defined Functions

- The Form
- Examples

3 Function Calls

4 Function Prototypes and Header Files

5 Assignment

Function Prototypes

- The function prototype must precede the function definition and usage.
- Place the prototype at the top of the implementation file (`.cpp`) in which the function is used.
- Or, place the prototype in a header (`.h`) file and include the header file in the implementation file.

Example of a Prototype

Function Prototype

```
float average(float a, float b, float c);

int main()
{
    :
    average(x, y, z)
    :
}

float average(float a, float b, float c)
{...}
```

- The prototype of the `average()` function.

Function Execution

- The values of the objects in the *actual-parameter-list* are passed to the corresponding objects in the *formal-parameter-list*.
- The *function-body* is executed.
- The returned value is substituted into the expression in place of the function reference in the calling function.

Examples of Programmer-Defined Functions

- Examples

- AverageFunc.cpp
- IsVowelFunc.cpp
- IsVowelFunc2.cpp, isvowel.cpp, isvowel.h
