Fri, Sep 1, 2017

- 1 Resizing the Window
 - The `FramebufferSize` Callback Function
 - The `setView()` Function
- 2 Fixing a Point
 - Fixing the Lower-Left Corner
 - Fixing the Center Point
 - Fixing an Arbitrary Point
- 3 Assignment

1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setView()` Function

2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

3 Assignment

Resizing the Window

- When the window is resized by the user, the framebuffer size callback function is automatically called.
- It is the responsibility of the framebuffer size callback function to create a projection matrix, based on the new dimensions of the window, and to pass it to the vertex shader.

The `ortho2D()` Function

The `ortho2D()` Function

```
mat4 ortho2D(int left, int right, int bottom, int top);
```

- The `ortho2D()` function will create the projection matrix if we provide it with the left, right, bottom, and top boundaries (in world coordinates) of the window.

- 1 Resizing the Window
 - The `FramebufferSize` Callback Function
 - The `setView()` Function
- 2 Fixing a Point
 - Fixing the Lower-Left Corner
 - Fixing the Center Point
 - Fixing an Arbitrary Point
- 3 Assignment

The FramebufferSize Callback Function

The FramebufferSize Callback Function

```
void framebufferSizeCB(GLFWwindow* window, int width,
    int height)
{
    // Use width and height to compute the new window bounds

    left = ...
    right = ...
    bottom = ...
    top = ...
    :
    mat4 proj = ortho2D(left, right, bottom, top);
    glUniformMatrix4fv(proj_loc, 1, GL_TRUE, proj);
    :
}
```

1 Resizing the Window

- The FramebufferSize Callback Function
- The `setView()` Function

2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

3 Assignment

The `setView()` Function

The `setView()` Function

```
void setView()  
{  
    proj = ortho2D(left, right, bottom, top);  
    glUniformMatrix4fv(proj_loc, 1, GL_TRUE, proj);  
}
```

- It is handy to place into a separate function the statements that create and transfer the projection matrix.
- It is ok to make `proj`, `proj_loc`, `left`, `right`, `bottom`, and `top` global variables.

The `setView()` Function

The `setView()` Function

```
void setView()  
{  
    proj = ortho2D(left, right, bottom, top);  
    glUniformMatrix4fv(proj_loc, 1, GL_TRUE, proj);  
}
```

- It is handy to place into a separate function the statements that create and transfer the projection matrix.
- It is ok to make `proj`, `proj_loc`, `left`, `right`, `bottom`, and `top` global variables.
- Why is it ok?

The FramebufferSize Callback Function

- The question is, how to recompute *left*, *right*, *bottom*, and *top* when the window is resized?

The FramebufferSize Callback Function

- The question is, how to recompute *left*, *right*, *bottom*, and *top* when the window is resized?
- Choose a point that is to be fixed.
 - Upper-left corner
 - Lower-left corner
 - Center
 - Etc.

Outline

- 1 Resizing the Window
 - The `FramebufferSize` Callback Function
 - The `setView()` Function
- 2 Fixing a Point
 - Fixing the Lower-Left Corner
 - Fixing the Center Point
 - Fixing an Arbitrary Point
- 3 Assignment

Fixing a Point

- We will label the new values *LEFT*, *RIGHT*, *BOTTOM*, and *TOP*.
- Suppose we keep the lower-left corner fixed.
- If the window is expanded, then the expansion will reveal more of the scene to the right and above.

Outline

- 1 Resizing the Window
 - The `FramebufferSize` Callback Function
 - The `setView()` Function
- 2 Fixing a Point
 - Fixing the Lower-Left Corner
 - Fixing the Center Point
 - Fixing an Arbitrary Point
- 3 Assignment

Lower-Left Corner Fixed

Lower-Left Corner Fixed

- In the diagram, left, right, bottom, top, width, and height are the “old” values and LEFT, RIGHT, BOTTOM, TOP, WIDTH, and HEIGHT are the “new” values.

Lower-Left Corner Fixed

- *left*, *right*, *bottom*, and *top* are in world coordinates.
- *width* and *height* are in screen coordinates.
- Be careful!

Lower-Left Corner Fixed

- *left*, *right*, *bottom*, and *top* are in world coordinates.
- *width* and *height* are in screen coordinates.
- Be careful!
- In the following formulas, lowercase letters ℓ , r , b , t , w , h represent the old values and uppercase letters L , R , B , T , W , H represent the new values.

Lower-Left Corner Fixed

- Clearly, $L = \ell$ and $B = b$.
- Also, we have the relation

$$\frac{R - L}{r - \ell} = \frac{W}{w}.$$

Lower-Left Corner Fixed

- Clearly, $L = \ell$ and $B = b$.
- Also, we have the relation

$$\frac{R - L}{r - \ell} = \frac{W}{w}.$$

- Therefore,

$$R = L + \left(\frac{W}{w} \right) (r - \ell).$$

Lower-Left Corner Fixed

- Clearly, $L = \ell$ and $B = b$.
- Also, we have the relation

$$\frac{R - L}{r - \ell} = \frac{W}{w}.$$

- Therefore,

$$R = L + \left(\frac{W}{w} \right) (r - \ell).$$

- Similarly,

$$T = B + \left(\frac{H}{h} \right) (t - b).$$

The framebufferSizeCB() Function

The framebufferSizeCB() Function

```
void framebufferSizeCB(int width, int height)
{
    // Compute new window boundaries

    right = left + (float)width/fb_width*(right - left);
    top = bottom + (float)height/fb_height*(top - bottom);

    setView();
    :
}
```

Outline

- 1 Resizing the Window
 - The `FramebufferSize` Callback Function
 - The `setView()` Function
- 2 Fixing a Point
 - Fixing the Lower-Left Corner
 - **Fixing the Center Point**
 - Fixing an Arbitrary Point
- 3 Assignment

Center Fixed

Center Fixed

- We may keep the center fixed.

The framebufferSizeCB() Function

The framebufferSizeCB() Function

```
void framebufferSizeCB(int width, int height)
{
    // Compute new window boundaries

    right = 0.5f*((1.0f + (float)width)/fb_width)*right +
        (1.0f - (float)width/fb_width*left);
    left = ...
    top = ...
    bottom = ...

    setView();
    :
}
```

Outline

- 1 Resizing the Window
 - The `FramebufferSize` Callback Function
 - The `setView()` Function
- 2 Fixing a Point
 - Fixing the Lower-Left Corner
 - Fixing the Center Point
 - Fixing an Arbitrary Point
- 3 Assignment

Fixing an Arbitrary Point

- We may keep any point fixed.
- If the window is expanded, then the expansion will reveal area to the left and right, and the bottom and bottom, in proportion to the fixed point's location.
- For example, if the point is $\frac{1}{6}$ of the way from left to right, then $\frac{1}{6}$ of the revealed area will be to the left and $\frac{5}{6}$ will be to the right.
- The same holds in the vertical direction.

Fixing an Arbitrary Point

Fixing an Arbitrary Point

Fixing an Arbitrary Point

- To keep the point (x_0, y_0) fixed, we must have the relation

$$\frac{x_0 - L}{x_0 - \ell} = \frac{W}{w}.$$

- Therefore,

$$L = x_0 - \left(\frac{W}{w} \right) (x_0 - \ell).$$

Fixing an Arbitrary Point

- The full set of equations is

$$L = x_0 - \left(\frac{W}{w}\right) (x_0 - \ell),$$

$$R = x_0 + \left(\frac{W}{w}\right) (r - x_0),$$

$$B = y_0 - \left(\frac{H}{h}\right) (y_0 - b),$$

$$T = y_0 + \left(\frac{H}{h}\right) (t - y_0).$$

The framebufferSizeCB() Function

The framebufferSizeCB() Function

```
void framebufferSizeCB(int width, int height)
{
    // Compute new window boundaries

    float x_0 = ...
    float y_0 = ...
    float ratio_w = (float)width/fb_width;
    float ratio_h = (float)height/fb_height;

    left = x_0 - ratio_w*(x_0 - left);
    right = x_0 + ratio_w*(right - x_0);
    bottom = y_0 - ratio_h*(y_0 - bottom);
    top = y_0 + ratio_h*(top - y_0);

    setView();
    :
}
```

Fixing an Arbitrary Point

- For example, if we wanted to keep the upper-right corner fixed, then $x_0 = r$, $y_0 = t$ and the equations become

$$L = r - \left(\frac{W}{w}\right)(r - \ell),$$

$$R = r,$$

$$B = t - \left(\frac{H}{h}\right)(t - b),$$

$$T = t.$$
