# jQuery and AJAX

# Outline

1

## jQuery and AJAX

# jQuery and AJAX

- The W3Schools website says “Without jQuery, AJAX coding can be a bit tricky!”

# jQuery and AJAX

- The W3Schools website says “Without jQuery, AJAX coding can be a bit tricky!”
- Really?

# The load() Function

## Linking to Javascript

```
$(selector).load(file-name)
```

- The jQuery `load()` function does what AJAX does when it assigns `responseText` to the `innerHTML` of an element.
- We do not need to create an `XMLHttpRequest` object.
- We do not need to invoke the `open()` and `send()` functions.
- We do not need to monitor the response.

# The load() Function

## Using .ajax()

```
function my_func()
{
    :
    $(document).ready(function () {
        :
        var my_val = $.ajax({parameters}).responseText;
        :
    });
});
```

- The jQuery ajax() function uses AJAX to send an HTTP request to the server.
- *parameters* is a list { . . . } of parameters.
- It executes when the function in which it is written is invoked.

# The load() Function

## Using .ajax()

```
var is_valid = $.ajax({
    type: "GET",
    url: "validate_uname.php?uname=" + uname;
    async: false;
}).responseText;
```

- The most important parameters are `type`, `url`, and `async`.
- In this example, `is_valid` receives the text that is output by `validate_uname.php`.

# Validating the user name

## Validating the user name

```
function validate()
{
    if (document.getElementById("name").value == "") {
        alert("Please enter your user name");
        return false;
    }

$(document).ready(function() {
    var uname = document.getElementById("uname").value;
    var in_use = $.ajax({
        type: "GET",
        url: "validate_uname.php?uname=" + uname,
        async: false
    }).responseText;

    if (in_use == "true")
        return false;
});
}
```
