Overview of
the x86
Architecture
Instruction Format
Registers
Data Types
The Run-time Stack
Assignment

- Each instruction is of the form
`[label:] mnemonic [operand1][, operand2][, operand3]`
- The number of operands is 0, 1, 2, or 3, depending on the mnemonic .
- Each operand is either
 - An immediate value,
 - A register, or
 - A memory address.

Source and Destination Operands

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture
Instruction Format
Registers
Data Types
The Run-time Stack
Assignment

- Each operand is either a **source operand** or an **destination operand**.
- A source operand, in general, may be
 - An immediate value,
 - A register, or
 - A memory address.
- A destination operand, in general, may be
 - A register, or
 - A memory address.

Source and Destination Operands

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- The standard interpretation of

`mnemonic operand1,operand2`

is that `operand1` is the destination and `operand2` is the source.

`operand1 ← operand1 op operand2`

- The Intel manuals are written according to the standard interpretation.

Source and Destination Operands

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- However, the gnu interpretation of

`mnemonic operand1,operand2`

is that `operand1` is the source and `operand2` is the destination.

`operand1 op operand2 → operand2`

- Therefore, we will have to interpret the information in the Intel manuals accordingly.

Instructions

The x86
Architecture

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- Not every logical combination of operands is permitted in every instruction.
- See the references
 - “IA-32 Intel Architecture Software Developer’s Manual Volume 2A: Instruction Set Reference, A-M”
 - “IA-32 Intel Architecture Software Developer’s Manual Volume 2B: Instruction Set Reference, N-Z”

Instructions

The x86 Architecture

Robb T.
Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- Different instructions require different numbers of operands.
- For example,
 - `hlt` - 0 operands
 - `inc` - 1 operand
 - `add` - 2 operands
 - `imul` - 1, 2, or 3 operands

Address Space

The x86 Architecture

Robb T.
Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- The memory addresses are 32 bits, so they can access up to 4 GB of memory.
- A global variable or function is referenced by its name, which is a label representing its address.
- Local variables are referenced by an offset from the base pointer, which holds the base address of the activation record on the stack.

Basic Registers

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- There are
 - Eight 32-bit “general-purpose” registers,
 - One 32-bit EFLAGS register,
 - One 32-bit instruction pointer register (*eip*), and
 - Other special-purpose registers.

The General-Purpose Registers

The x86 Architecture

Robb T.
Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- The eight 32-bit **general-purpose registers** are `eax`, `ebx`, `ecx`, `edx`, `esi`, `edi`, `ebp`, and `esp`.
- For calculations, we will use `eax`, `ebx`, `ecx`, and `edx`.
- Register `esp` is the **stack pointer**.
- Register `ebp` is the **base pointer**.
- Registers `esi` and `edi` are **source** and **destination index registers** for array and string operations.

The General-Purpose Registers

The x86 Architecture

Robb T. Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- The registers `eax`, `ebx`, `ecx`, and `edx` may be accessed as 32-bit, 16-bit, or 8-bit registers.
- The other four registers can be accessed as 32-bit or 16-bit.
- For example,
 - Register `eax` represents a 32-bit quantity.
 - The low-order two bytes of `eax` may be accessed through the name `ax`.
 - The high-order byte of `ax` is named `ah`.
 - The low-order byte of `ax` is named `al`.

The General-Purpose 32-Bit Registers

Registers

Data Types

The Run-time Stack

Assignment

The General-Purpose 16-Bit Registers

The x86 Architecture

Robb T.
Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

31	16	15	0		
				ax	Accumulator
				bx	
				cx	
				dx	
				bp	Base pointer
				si	Array source
				di	Array destination
				sp	Stack pointer

The General-Purpose 8-Bit Registers

The x86 Architecture

Robb T.
Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

31	16 15	8 7	0	
		ah	al	Accumulator
		bh	bl	
		ch	cl	
		dh	dl	
		bp		Base pointer
		si		Array source
		di		Array destination
		sp		Stack pointer

EFLAGS Register

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- The various bits of the 32-bit EFLAGS register are set (1) or reset (0) according to the results of certain operations.
- We will be interested in the bits
 - CF - carry flag
 - PF - parity flag
 - ZF - zero flag
 - SF - sign flag

Instruction Pointer

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- Finally, there is the `eip` register, which is the **instruction pointer**.
- Register `eip` holds the address of the next instruction to be executed.
- We should never change the value of `eip` directly. It will be updated automatically as necessary.

Data Types

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- There are 5 integer data types.
 - Byte - 8 bits.
 - Word - 16 bits.
 - Doubleword - 32 bits.
 - Quadword - 64 bits.
 - Double quadword - 128 bits.
- We will use doublewords (for `ints`) unless we have a specific need for one of the other types.

The Run-time Stack

The x86 Architecture

Robb T.
Koether

Overview of the x86 Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- The **run-time stack** supports procedure calls and the passing of parameters between procedures.
- The stack is located in memory.
- The stack grows towards low memory.
 - When we push a value, esp is decremented.
 - When we pop a value, esp is incremented.

Using the Run-time Stack

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- Typically, if an operation produces a result, we will push that result onto the stack.
- The next operation, if it expects a previous result, will pop it off the stack.
- The alternative is to use the registers to pass results, but that is much more complicated since we would have to keep track of which registers were free.

Function Calls and the Base Pointer

The x86
Architecture

Robb T.
Koether

Overview of
the x86
Architecture

Instruction Format

Registers

Data Types

The Run-time Stack

Assignment

- When we make a function call, we use the base pointer `ebp` to store the location of the top of the stack `esp` before the function call.

$$esp \rightarrow ebp$$

- Then we push the parameters and local variables of the function onto the stack.
- When we return from the function, we use the base pointer to restore the top of the stack to its previous location.

$$ebp \rightarrow esp$$
