# Greedy Algorithms

## Definition (Greedy Algorithms)

A **greedy algorithm** is an algorithm that, like greedy people, grabs what looks best in the short run, whether or not it is best in the long run.

- Greedy algorithms optimize **locally**, but not necessarily **globally**.
- The benefit of greedy algorithms is that they are simple and fast.

# Approximate Algorithms

## Definition (Approximate Algorithm)

An **approximate algorithm** is an algorithm that gives a good solution, but not necessarily the best solution.

- We will look at two greedy, approximate algorithms to handle the Traveling Salesman Problem.

# The Nearest-Neighbor Algorithm

## Definition (Nearest-Neighbor Algorithm)

The **Nearest-Neighbor Algorithm** begins at any vertex and follows the edge of least weight from that vertex. At every subsequent vertex, it follows the edge of least weight that leads to a city not yet visited, until it returns to the starting point.

# The Nearest-Neighbor Algorithm

## Example (Nearest-Neighbor Algorithm)

- We ended up with the circuit *ABJCEDFGHIA*.
- The length is 94 miles.
- Is it possible to do better?

- 4 The Repetitive Nearest-Neighbor Algorithm**
- 5 The Cheapest-Link Algorithm

# The Repetitive Nearest-Neighbor Algorithm

## Definition (Repetitive Nearest-Neighbor Algorithm)

The **Repetitive Nearest-Neighbor Algorithm** applies the nearest-neighbor algorithm repeatedly, using each of the vertices as a starting point. It selects the starting point that produced the shortest circuit.

# The Repetitive Nearest-Neighbor Algorithm

## Example (Repetitive Nearest-Neighbor Algorithm)

- Re-do the previous example, starting at city  $B$ .
- Re-do the previous example, starting at city  $C$ .
- Did we get a better solution?

- 2 Greedy and Approximate Algorithms
- 3 The Nearest-Neighbor Algorithm
- 4 The Repetitive Nearest-Neighbor Algorithm
- 5 The Cheapest-Link Algorithm**

# The Cheapest-Link Algorithm

## Definition (Cheapest-Link Algorithm)

The **Cheapest-Link Algorithm** begins with the edge of least weight and makes it part of the circuit. Then it selects the edge of second-smallest weight, and so on. Once a vertex has two selected edges, no more edges of that vertex are considered and we must avoid creating a circuit prematurely. Eventually the edges will form a circuit.
