Fri, Sep 6, 2019

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

# Resizing the Window

- When the window is resized by the user, the framebuffer size (or window size) callback function is automatically called.
- It is the responsibility of the framebuffer size callback function to create a projection matrix, based on the new dimensions of the window, and to pass it to the vertex shader.

# The `ortho2D()` Function

## The `ortho2D()` Function

```
mat4 ortho2D(int xmin, int xmax, int ymin, int ymax);
```

- The `ortho2D()` function will create the projection matrix if we provide it with the left, right, bottom, and top boundaries (in world coordinates) of the window, which we are naming `xmin`, `xmax`, `ymin`, and `ymax`.

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

# The framebufferSize Callback Function

## The framebufferSize Callback Function

```
void framebufferSizeCB(GLFWwindow* window, int width,
    int height)
{
// Use width and height to compute the new
// window boundaries

    xmin = ...
    xmax = ...
    ymin = ...
    ymax = ...
    :
mat4 proj = ortho2D(xmin, xmax, ymin, ymax);
    glUniformMatrix4fv(proj_loc, 1, GL_TRUE, proj);
    :
}
```

- We will use the global variables `xmin`, `xmax`, `ymin`, and `ymax` for

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

# The setProj() Function

## The setProj() Function

```
void setProj()  
{  
    proj = ortho2D(xmin, xmax, ymin, ymax);  
    glUniformMatrix4fv(proj_loc, 1, GL_TRUE, proj);  
}
```

- It is handy to place into a separate function the statements that create and transfer the projection matrix.
- It is ok to make `proj`, `proj_loc`, `xmin`, `xmax`, `ymin`, and `ymax` global variables.

# The setProj() Function

## The setProj() Function

```
void setProj()  
{  
    proj = ortho2D(xmin, xmax, ymin, ymax);  
    glUniformMatrix4fv(proj_loc, 1, GL_TRUE, proj);  
}
```

- It is handy to place into a separate function the statements that create and transfer the projection matrix.
- It is ok to make `proj`, `proj_loc`, `xmin`, `xmax`, `ymin`, and `ymax` global variables.
- Why is it ok?

# The framebufferSize Callback Function

- The question is, how to recompute  $xmin$ ,  $xmax$ ,  $ymin$ , and  $ymax$  when the window is resized?

# The FramebufferSize Callback Function

- The question is, how to recompute  $xmin$ ,  $xmax$ ,  $ymin$ , and  $ymax$  when the window is resized?
- Choose a point that is to be fixed.
  - Upper-left corner
  - Lower-left corner
  - Center
  - Etc.

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

# Fixing a Point

- We will label the new values  $XMIN$ ,  $XMAX$ ,  $YMIN$ , and  $YMAX$ .
- Suppose we keep the lower-left corner fixed.
- If the window is expanded, then the expansion will reveal more of the scene to the right and above.

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

# Lower-Left Corner Fixed

## Lower-Left Corner Fixed

- In the diagram,  $xmin$ ,  $xmax$ ,  $ymin$ ,  $ymax$ ,  $width$ , and  $height$  are the “old” values and  $XMIN$ ,  $XMAX$ ,  $YMIN$ ,  $YMAX$ ,  $WIDTH$ , and  $HEIGHT$  are the “new” values.

# Lower-Left Corner Fixed

- $xmin$ ,  $xmax$ ,  $ymin$ , and  $ymax$  are in world coordinates.
- $width$  and  $height$  are in screen coordinates.
- Be careful.

# Lower-Left Corner Fixed

- $xmin$ ,  $xmax$ ,  $ymin$ , and  $ymax$  are in world coordinates.
- $width$  and  $height$  are in screen coordinates.
- Be careful.
- Be Careful!

# Lower-Left Corner Fixed

- $xmin$ ,  $xmax$ ,  $ymin$ , and  $ymax$  are in world coordinates.
- $width$  and  $height$  are in screen coordinates.
- Be careful.
- Be Careful!
- BE CAREFUL!!!

# Lower-Left Corner Fixed

- Clearly,  $XMIN = xmin$  and  $YMIN = ymin$ .
- Also, we have the relation

$$\frac{YMAX - XMIN}{xmax - xmin} = \frac{WIDTH}{width}.$$

# Lower-Left Corner Fixed

- Clearly,  $XMIN = xmin$  and  $YMIN = ymin$ .
- Also, we have the relation

$$\frac{YMAX - XMIN}{xmax - xmin} = \frac{WIDTH}{width}.$$

- Therefore,

$$YMAX = XMIN + \left( \frac{WIDTH}{width} \right) (xmax - xmin).$$

# Lower-Left Corner Fixed

- Clearly,  $XMIN = xmin$  and  $YMIN = ymin$ .
- Also, we have the relation

$$\frac{YMAX - XMIN}{xmax - xmin} = \frac{WIDTH}{width}.$$

- Therefore,

$$YMAX = XMIN + \left( \frac{WIDTH}{width} \right) (xmax - xmin).$$

- Similarly,

$$YMAX = YMIN + \left( \frac{HEIGHT}{height} \right) (ymax - ymin).$$

# The framebufferSizeCB() Function

## The framebufferSizeCB() Function

```
void framebufferSizeCB(int width, int height)
{
    // Compute new window boundaries

    xmax = xmin + (float)width/fb_width*(xmax - xmin);
    ymax = ymin + (float)height/fb_height*(ymax - ymin);

    setProj();
    :
}
```

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

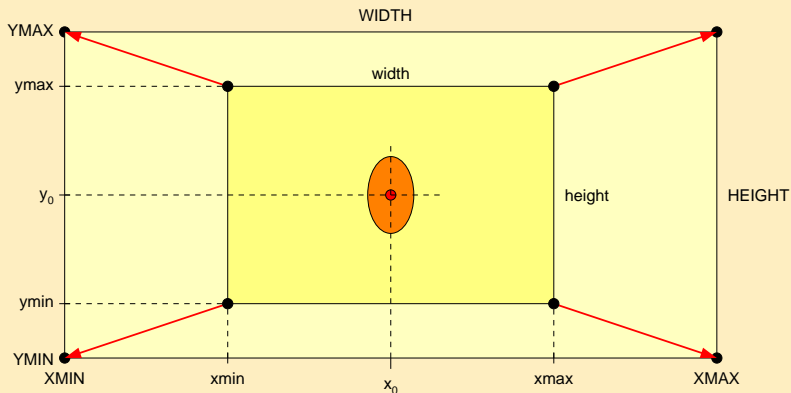

## 2 Fixing a Point

- Fixing the Lower-Left Corner
- **Fixing the Center Point**
- Fixing an Arbitrary Point

# Center Fixed

## Center Fixed

- We may keep the center fixed.

# The framebufferSizeCB() Function

## The framebufferSizeCB() Function

```
void framebufferSizeCB(int width, int height)
{
    // Compute new window boundaries

    xmin = ...
    xmax = 0.5*((xmax + xmin)
               + (float)(width/fb_width)*(xmax - xmin));
    ymin = ...
    ymax = ...

    setProj();
    :
}
```

- This may produce the wrong results. How so?

## 1 Resizing the Window

- The `FramebufferSize` Callback Function
- The `setProj()` Function

## 2 Fixing a Point

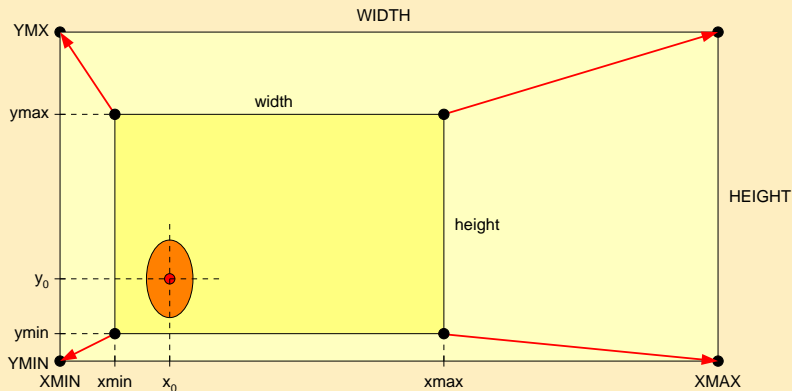

- Fixing the Lower-Left Corner
- Fixing the Center Point
- Fixing an Arbitrary Point

# Fixing an Arbitrary Point

- We may keep any point fixed.
- If the window is expanded, then the expansion will reveal area to the left and right, and the bottom and top, in proportion to the fixed point's location.
- For example, if the point is  $\frac{1}{6}$  of the way from  $x_{\min}$  to  $x_{\max}$ , then  $\frac{1}{6}$  of the revealed area will be to the left and  $\frac{5}{6}$  will be to the  $x_{\max}$ .
- The same holds in the vertical direction.

# Fixing an Arbitrary Point

## Fixing an Arbitrary Point

# Fixing an Arbitrary Point

- To keep the point  $(x_0, y_0)$  fixed, we must have the relation

$$\frac{x_0 - XMIN}{x_0 - xmin} = \frac{WIDTH}{width}.$$

- Therefore,

$$XMIN = x_0 - \left( \frac{WIDTH}{width} \right) (x_0 - xmin).$$

# Fixing an Arbitrary Point

- The full set of equations is

$$XMIN = x_0 - \left( \frac{WIDTH}{width} \right) (x_0 - xmin),$$

$$XMAX = x_0 + \left( \frac{WIDTH}{width} \right) (xmax - x_0),$$

$$YMIN = y_0 - \left( \frac{HEIGHT}{height} \right) (y_0 - ymin),$$

$$YMAX = y_0 + \left( \frac{HEIGHT}{height} \right) (ymax - y_0).$$

# The framebufferSizeCB() Function

## The framebufferSizeCB() Function

```
void framebufferSizeCB(int width, int height)
{
    // Compute new window boundaries

    float x_0 = ...
    float y_0 = ...
    float ratio_w = (float)width/fb_width;
    float ratio_h = (float)height/fb_height;

    xmin = x_0 - ratio_w*(x_0 - xmin);
    xmax = x_0 + ratio_w*(xmax - x_0);
    ymin = y_0 - ratio_h*(y_0 - ymin);
    ymax = y_0 + ratio_h*(ymax - y_0);

    setProj();
    :
}
```

# Fixing an Arbitrary Point

- For example, if we wanted to keep the upper-right corner fixed, then  $x_0 = xmax$ ,  $y_0 = ymax$  and the equations become

$$XMIN = xmax - \left( \frac{WIDTH}{width} \right) (xmax - xmin),$$

$$XMAX = xmax,$$

$$YMIN = ymax - \left( \frac{HEIGHT}{width} \right) (ymax - ymin),$$

$$YMAX = ymax.$$
